~~Settlers of Catan~~ A board game is played on a hexagonal grid of 19 tiles. A 'traveler' token starts on the center tile. Each turn a die is rolled to determine what neighboring tile the traveler moves to (all six directions equally likely). The turn that the traveler leaves the board, the game ends. What is the expected number of turns of the game?

A diagram of a hexagonal lattice structure, likely representing a honeycomb lattice. The lattice consists of 37 cells, each labeled with a number from 0 to 36. The cells are arranged in a hexagonal pattern, with the central cell labeled 0. The cells are colored white, and the edges are colored blue. The cells are labeled with black numbers, and each cell contains a small red dot. The cells are arranged in a hexagonal pattern, with the central cell at the bottom center.

We wish to find the expected value of the number of turns in the game, which we denote N .

The dice is truly random, so there is no upper bound on N . We note that this game is really akin to a Markov chain, in that it doesn't matter what the past states are.

In order to get the expected number of steps, we find t_0 , where

$$t \equiv N\mathbf{1}$$

Here, $\mathbf{1}$ is a vector whose entries are all 1.

[illegible]

Finally, we see that $t_0 = \boxed{\frac{213}{29} \approx 7.345}$
